Playful Python

I believe you can learn serious things through silly games.

I'd like to make this into a book or something, similar to the Python bioinformatics/data science (https://github.com/kyclark/practical_python_for_data_science) repo. I think you will learn best by doing, so I think I will write this as a loose collection of exercises that spell out the skills I aim to teach with each exercise. I will create descriptions for each exercise with examples of how the program should work along with a test suite. You will need to write the program that satisfies the test suite.

I think I'm going to present this differently from other material in that I won't necessarily show you beforehand what you need to write a program. I'll describe what the program should do and provide some discussion about how to write it. I'll also create an appendix with short example of how to do things like read/write from/to a file, process all the files in a directory, extract k-mers from a string, etc. I'll provide some building blocks, but I want you to figure out how to put the pieces together!

new.py

I provide a program in the bin directory called new.py that will help you stub out new Python programs using the fabulous argparse module to parse the command line arguments and options for your programs. I highly recommend you start every new program with this. For example, if the README.md says "Write a Python program called abc.py that ...", then you should do this:

\$ new.py abc

This will create a new file called abc.py (that has been made executable with chmod +x, if your operating system supports that) that has example code for you to start writing your program. It's best to put new.py into your \$PATH or alter your \$PATH to include the directory where it's located. FWIW, I always create a \$HOME/.local/bin that I add to my \$PATH for programs like this.

How to Use

First use the GitHub interface to "fork" this repository into your own account. Then do git clone of *your* repository to get a local copy. Inside that checkout, do:

git remote add upstream https://github.com/kyclark/playful_python.git

so that you can do git pull upstream master to get updates. When you create new files, git add/commit/push them to *your* repository. (Please do not create pull requests on my repository – unless, of course, you have suggestions for improving my repo!).

This is a work in progress. If you see a directory contains a README.md, solution.py, Makefile, and test.py, then it's likely ready to be solved.

Structure

Right now, I'm not sure how I'll structure the exercises. I wouldn't mind if you just randomly chose one and see how it goes. They vary quite a bit in difficulty, so maybe I'll just give them 1, 2, or 3 stars to indicate easy to hard. See OUTLINE.md for more.

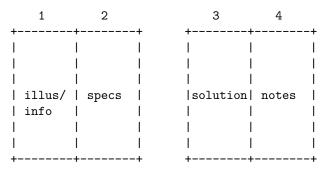

Author

Ken Youens-Clark (BA, MS) is a Sr. Scientific Programmer in the lab of Dr. Bonnie Hurwitz at the University of Arizona. He started programming at his first job out of college. He's work in the field of bioinformatics since 2001, and enjoys helping people to learn programming. When he's not working, he likes playing music, riding bikes, cooking, and being with his wife and children.

Playful Python Outline

I aim to have 40-50 programs complete with specs, examples, inputs, and test suites. They won't necessarily have a specific order, but they will be grouped into easiest/harder/hardest categories. As many programs use common ideas (e.g., regular expressions, graphs, infinite loops), there will be an appendix section with explanations of how to explore those ideas.

I have in mind a layout where each program gets four pages:

- 1. If a short program, perhaps an illustration; if longer, maybe some background or hints.
- 2. The README.md information (specs, example output)
- 3. The solution.py contents
- 4. Annotation of the solution with comments on lines, sections

Programs

"The only way to learn a new programming language is by writing programs in it." - Dennis Ritchie

The goal is to get the reader to become a writer – to try to solve the problems. One technique in teaching is to first present a problem without showing how to solve it. Once the student engages with the problem, they find they want and need the object of the lesson. Each program is intended to flex some programming technique or idea like playing with lists or contemplating regular expressions or using dictionaries. By using argparse for the programs, we also cover validation of user input.

Easiest

• article: Select "a" or "an" depending on the given argument

- howler: Uppercase input text so they YELL AT YOU LIKE "HOWLER" MESSAGES IN HARRY POTTER. (Could also be called "OWEN MEANY"?)
- jump_the_five: Numeric encryption based on "The Wire."
- bottles_of_beer: Produce the "Bottle of Beer on the Wall" song. Explores the basic idea of an algorithm and challenges the programmer to format strings.
- picnic: Write the picnic game. Uses input, lists.
- apples_and_bananas: Substitute vowels in text, e.g., "bananas" -> "bononos". While the concept is substitution of characters in a string which is actually trivial, it turns out there are many (at least 7) decent ways to accomplish this task!
- gashlycrumb: Create a morbid lookup table from text. Naturual use of dictionaries.
- movie_reader: Print text character-by-character with pauses like in the movies. How to read text by character, use STDOUT/flush, and pause the program.
- palindromes: Find palindromes in text. Reading input, manipulation of strings.
- ransom_note: Transform input text into "RaNSom cASe". Manipulation of text.
- rhymer: Produce rhyming "words" from input text.
- rock_paper_scissors: Write Rock, Paper, Scissors game. Infinite loops, dictionaries.

Harder

- abuse: Generate insults from lists of adjectives and nouns. Use of randomness, sampling, and lists.
- bacronym: Retrofit words onto acronyms. Use of randomness and dictionaries.
- blackjack: Play Blackjack (card game). Use of randomness, combinations, dictionaries.
- family_tree: Use GraphViz to visualize a family tree from text. Parsing text, creating graph structures, creating visual output.
- **gematria**: Calculate numeric values of words from characters. Manipulation of text, use of higher-order functions.
- guess: Write a number-guessing game. Use of randomness, validation/coercion of inputs, use of exceptions.
- **kentucky_fryer**: Turn text into Southern American English. Parsing, manipulation of text.
- mad_libs: TBD
- markov_words: Markov chain to generate words. Use of n-grams/k-mers, graphs, randomness, logging.

- **piggie**: Encode text in Pig Latin. Use of regular expressions, text manipulation.
- sound: Use Soundex to find rhyming words from a word list.
- **substring**: Write a game to guess words sharing a common substring. Dictionaries, k-mers/n-grams.
- tictactoe: Write a Tic-Tac-Toe game. Randomness, state.
- twelve_days_of_christmas: Produce the "12 Days of Christmas" song. Algorihtms, loops.
- war: Play the War card game. Combinations, randomness.

Hardest

- anagram: Find anagrams of text. Combinations, permutations, dictionaries.
- hangman: Write a Hangman (word/letter-guessing game). Randomness, game state, infinite loops, user input, validation.
- markov_chain: Markov chain to generate text. N-grams at word level, parsing text, list manipulations.
- morse: Write a Morse encoder/decoder. Dictionaries, text manipulation.
- rot13: ROT13-encode input text. Lists, encryption.

Article Selector

Write a Python program called article.py that will select a or an for a given word depending on whether the word starts with a consonant or vowel, respectively.

article Solution

```
1 #!/usr/bin/env python3
2 """Article selector"""
4 import argparse
5 import os
6 import sys
7
8
9 # -----
10 def get_args():
      """Get command-line arguments"""
11
12
13
      parser = argparse.ArgumentParser(
14
         description='Article selector',
         formatter_class=argparse.ArgumentDefaultsHelpFormatter)
15
16
17
      parser.add_argument('word', metavar='str', help='Word')
18
19
      return parser.parse_args()
20
21
22 # -----
23 def main():
      """Make a jazz noise here"""
24
25
26
      args = get_args()
      word = args.word
27
28
      article = 'an' if word[0].lower() in 'aeiou' else 'a'
29
30
      print('{} {}'.format(article, word))
31
32 # -----
33 if __name__ == '__main__':
34
      main()
```

Jump the Five

Write a program called jump.py that will encode any number using "jump-the-five" algorithm that selects as a replacement for a given number the number that is opposite the number on a US telephone pad if you jump over the 5. The numbers 5 and 9 will exchange with each other. So, "1" jumps the 5 to become "9," "6" jumps the 5 to become "4," "5" becomes "0," etc.

```
1 2 3
4 5 6
7 8 9
# 0 *
```

If given no arguments, print a usage statement.

```
$ ./jump.py
Usage: jump.py NUMBER
$ ./jump.py 555-1212
000-9898
$ ./jump.py 'Call 1-800-329-8044 today!'
Call 9-255-781-2566 today!
```

jump_the_five Solution

```
1 #!/usr/bin/env python3
2 """Jump the Five"""
4 import os
5 import sys
7
8 # -----
9 def main():
      """Make a jazz noise here"""
10
11
12
      args = sys.argv[1:]
13
14
      if len(args) != 1:
15
          print('Usage: {} NUMBER'.format(os.path.basename(sys.argv[0])))
16
          sys.exit(1)
17
      num = args[0]
18
19
      jumper = {
20
          '1': '9',
          '2': '8',
21
          '3': '7',
22
          '4': '6',
23
          '5': '0',
24
25
          '6': '4',
26
          '7': '3',
27
          '8': '2',
          '9': '1',
28
29
          '0': '5'
      }
30
31
32
      for char in num:
          print(jumper[char] if char in jumper else char, end='')
33
34
      print()
35
36
37 # -----
38 if __name__ == '__main__':
     main()
39
```

Picnic

Write a Python program called picnic.py that accepts one or more positional arguments as the items to bring on a picnic. In response, print "You are bringing ..." where "..." should be replaced according to the number of items where:

- 1. If one item, just state, e.g., if chips then "You are bringing chips."
- 2. If two items, put "and" in between, e.g., if chips soda then "You are bringing chips and soda."
- 3. If three or more items, place commas between all the items INCLUD-ING BEFORE THE FINAL "and" BECAUSE WE USE THE OXFORD COMMA, e.g., if chips soda cupcakes then "You are bringing chips, soda, and cupcakes."

```
$ ./picnic.py
usage: picnic.py [-h] str [str ...]
picnic.py: error: the following arguments are required: str
$ ./picnic.py -h
usage: picnic.py [-h] str [str ...]
Picnic game
positional arguments:
              Item(s) to bring
optional arguments:
  -h, --help show this help message and exit
$ ./picnic.py chips
You are bringing chips.
$ ./picnic.py "potato chips" salad
You are bringing potato chips and salad.
$ ./picnic.py "potato chips" salad soda cupcakes
You are bringing potato chips, salad, soda, and cupcakes.
```

picnic Solution

```
1 #!/usr/bin/env python3
2 """Picnic game"""
4 import argparse
5
6
7 # -----
8 def get_args():
      """Get command-line arguments"""
9
10
      parser = argparse.ArgumentParser(
11
12
          description='Picnic game',
13
          formatter_class=argparse.ArgumentDefaultsHelpFormatter)
14
15
      parser.add_argument('item',
16
                       metavar='str',
17
                       nargs='+',
                       help='Item(s) to bring')
18
19
20
      return parser.parse_args()
21
22
23 # -----
24 def main():
25
      """Make a jazz noise here"""
26
27
      args = get_args()
      items = args.item
28
29
      num = len(items)
30
31
      bringing = items[0] if num == 1 else ' and '.join(
32
          items) if num == 2 else ', '.join(items[:-1] + ['and ' + items[-1]])
33
      print('You are bringing {}.'.format(bringing))
34
35
36
37 # -----
38 if __name__ == '__main__':
39
     main()
```

Apples and Bananas

```
Perhaps you remember the children's song "Apples and Bananas"?

I like to eat, eat apples and bananas
I like to eat, eat apples and bananas

I like to ate, ate ay-ples and bananas
I like to ate, ate ay-ples and bananas
I like to ate, ate ay-ples and banay-nays
I like to eat, eat, eat ee-ples and bee-nee-nees
I like to eat, eat, eat ee-ples and bee-nee-nees
```

Write a Python program called apples.py that will turn all the vowels in some given text in a single positional argument into just one -v|--vowel (default a) like this song. It should complain if the --vowel argument isn't a single, lowercase vowel (hint, see choices in the argparse documentation). If the given text argument is a file, read the text from the file. Replace all vowels with the given vowel, both lower- and uppercase.

```
$ ./apples.py
usage: apples.py [-h] [-v str] str
apples.py: error: the following arguments are required: str
$ ./apples.py -h
usage: apples.py [-h] [-v str] str
Apples and bananas
positional arguments:
                       Input text or file
optional arguments:
 -h, --help
                       show this help message and exit
  -v str, --vowel str The only vowel allowed (default: a)
$ ./apples.py -v x foo
usage: apples.py [-h] [-v str] str
apples.py: error: argument -v/--vowel: invalid choice: 'x' (choose from 'a', 'e', 'i', 'o',
$ ./apples.py foo
faa
$ ./apples.py ../inputs/fox.txt
Tha qaack brawn fax jamps avar tha lazy dag.
```

apples_and_bananas Solution

```
1 #!/usr/bin/env python3
3 import argparse
4 import os
5 import re
6 import sys
7
8
9 # -----
10 def get_args():
       """get command-line arguments"""
11
       parser = argparse.ArgumentParser(
12
13
          description='Apples and bananas',
14
          formatter_class=argparse.ArgumentDefaultsHelpFormatter)
15
16
       parser.add_argument('text', metavar='str', help='Input text or file')
17
       parser.add_argument('-v',
18
19
                         '--vowel',
20
                         help='The vowel(s) allowed',
21
                         metavar='str',
22
                         type=str,
23
                         default='a',
                         choices=list('aeiou'))
24
25
26
       return parser.parse_args()

33
      text = args.text
34
       vowel = args.vowel
35
       if os.path.isfile(text):
36
37
          text = open(text).read()
38
39
       # Method 1: Iterate every character
40
       # new_text = []
41
       # for char in text:
42
           if char in 'aeiou':
       #
43
                new_text.append(vowel)
```

```
elif char in 'AEIOU':
44
45
                 new_text.append(vowel.upper())
46
47
                 new_text.append(char)
48
       # text = ''.join(new_text)
49
50
        # Method 2: str.replace
        # for v in 'aeiou':
51
             text = text.replace(v, vowel).replace(v.upper(), vowel.upper())
52
53
54
       # Method 3: Use a list comprehension
55
       # new_text = [
             vowel if c in 'aeiou' else vowel.upper() if c in 'AEIOU' else c
56
57
             for c in text
58
       # ]
       # text = ''.join(new_text)
59
60
        # Method 4: Define a function, use list comprehension
61
62
       def new_char(c):
           return vowel if c in 'aeiou' else vowel.upper() if c in 'AEIOU' else c
63
64
        # text = ''.join([new_char(c) for c in text])
65
66
67
        # Method 5: Use a `map` to iterate with a `lambda`
        # text = ''.join(
68
69
       #
             map(
70
                 lambda c: vowel if c in 'aeiou' else vowel.upper()
71
                 if c in 'AEIOU' else c, text))
72
       # Method 6: `map` with the function
73
74
       text = ''.join(map(new_char, text))
75
       # Method 7: Regular expressions
76
77
        # text = re.sub('[aeiou]', vowel, text)
       # text = re.sub('[AEIOU]', vowel.upper(), text)
78
79
80
       print(text.rstrip())
81
82
83 # -----
84 if __name__ == '__main__':
       main()
85
```

Howler

Write a Python program howler.py that will uppercase all the text from the command line or from a file.

```
$ ./howler.py
usage: howler.py [-h] [-o str] STR
howler.py: error: the following arguments are required: STR
$ ./howler.py -h
usage: howler.py [-h] [-o str] STR
Howler (upper-case input)
positional arguments:
 STR
                        Input string or file
optional arguments:
 -h, --help
                        show this help message and exit
 -o str, --outfile str
                        Output filename (default: )
$ ./howler.py 'One word: Plastics!'
ONE WORD: PLASTICS!
$ ./howler.py ../inputs/fox.txt
THE QUICK BROWN FOX JUMPS OVER THE LAZY DOG.
```

howler Solution

```
1 #!/usr/bin/env python3
 2 """Howler"""

Bottles of Beer Song

Write a Python program called bottles.py that takes a single option $-n|--num_bottles$ which is an positive integer (default 10) and prints the "bottles of beer on the wall song." If the -n argument is less than 1, die with "N () must be a positive integer". The program should also respond to -h|--help with a usage statement.

I'd encourage you to think about the program as a formal algorithm. Read the introduction to Jeff Erickson's book *Algorithms* available here:

- http://jeffe.cs.illinois.edu/teaching/algorithms/#book
- http://jeffe.cs.illinois.edu/teaching/algorithms/book/00-intro.pdf

You are going to need to count down, so you'll need to consider how to do that. First, let's examine a list and see how it can be sorted and reversed. We've already used the sorted function, but we haven't really talked about the list class's sort method. Note that the former does not mutate the list itself:

```
>>> a = ['foo', 'bar', 'baz']
>>> sorted(a)
['bar', 'baz', 'foo']
>>> a
['foo', 'bar', 'baz']
But the sort method does:
>>> a.sort()
>>> a
['bar', 'baz', 'foo']
Also, note what is returned by sort:
>>> type(a.sort())
<type 'NoneType'>
So if you did this, you'd destroy your data:
>>> a = a.sort()
>>> a
```

As with sort/sorted, so it goes with reverse/reversed. The past participle version returns a new copy of the data without affecting the original and is therefore the safest bet to use:

```
>>> a = ['foo', 'bar', 'baz']
>>> a
['foo', 'bar', 'baz']
```

```
>>> reversed(a)
treverseiterator object at 0x10f0d61d0>
>>> list(reversed(a))
['baz', 'bar', 'foo']
>>> a
['foo', 'bar', 'baz']
Compare with:
>>> a.reverse()
>>> a
['baz', 'bar', 'foo']
Given that and your knowledge of how range works, can you figure out how to
count down, say, from 10 to 1?
$ ./bottles.py -h
usage: bottles.py [-h] [-n INT]
Bottles of beer song
optional arguments:
 -h, --help
                        show this help message and exit
  -n INT, --num_bottles INT
$ ./bottles.py --help
usage: bottles.py [-h] [-n INT]
Bottles of beer song
optional arguments:
 -h, --help
                        show this help message and exit
 -n INT, --num_bottles INT
                        How many bottles (default: 10)
$ ./bottles.py -n 1
1 bottle of beer on the wall,
1 bottle of beer,
Take one down, pass it around,
O bottles of beer on the wall!
$ ./bottles.py | head
10 bottles of beer on the wall,
10 bottles of beer,
Take one down, pass it around,
9 bottles of beer on the wall!
9 bottles of beer on the wall,
9 bottles of beer,
Take one down, pass it around,
```

8 bottles of beer on the wall!

bottles of beer Solution

```
1 #!/usr/bin/env python3
3 import argparse
4 import sys
5 from dire import die
7
8
9 def get_args():
       """get command-line arguments"""
10
       parser = argparse.ArgumentParser(
11

```

Gashlycrumb

Write a Python program called gashlycrumb.py that takes a letter of the alphabet as an argument and looks up the line in a -f|--file argument (default gashlycrumb.txt) and prints the line starting with that letter.

```
$ ./gashlycrumb.py
usage: gashlycrumb.py [-h] [-f str] str
gashlycrumb.py: error: the following arguments are required: str
$ ./gashlycrumb.py -h
usage: gashlycrumb.py [-h] [-f str] str
Gashlycrumb
positional arguments:
 str
                      Letter
optional arguments:
  -h, --help
                      show this help message and exit
  -f str, --file str Input file (default: gashlycrumb.txt)
$ ./gashlycrumb.py 3
I do not know "3".
$ ./gashlycrumb.py CH
"CH" is not 1 character.
$ ./gashlycrumb.py a
A is for Amy who fell down the stairs.
$ ./gashlycrumb.py z
Z is for Zillah who drank too much gin.
```

If you are not familiar with the work of Edward Gorey, please stop and go read about him immediately, e.g. https://www.brainpickings.org/2011/01/19/edward-gorey-the-gashlycrumb-tinies/!

Write your own version of Gorey's text and pass in your version as the --file.

Write an interactive version that takes input directly from the user:

```
$ ./gashlycrumb_i.py
Please provide a letter [! to quit]: a
A is for Amy who fell down the stairs.
Please provide a letter [! to quit]: b
B is for Basil assaulted by bears.
Please provide a letter [! to quit]: !
Bye
```

```

Abuse

Write a Python program called abuse.py that generates some -n|--number of insults (default 3) by randomly combining some number of -a|--adjectives (default 2) with a noun (see below). Be sure your program accepts a -s|--seed argument (default None) to pass to random.seed.

Adjectives:

bankrupt base caterwauling corrupt cullionly detestable dishonest false filth-some filthy foolish foul gross heedless indistinguishable infected insatiate irk-some lascivious lecherous loathsome lubbery old peevish rascaly rotten ruinous scurilous scurvy slanderous sodden-witted thin-faced toad-spotted unmannered vile wall-eyed

Nouns:

Judas Satan ape ass barbermonger beggar block boy braggart butt carbuncle coward coxcomb cur dandy degenerate fiend fishmonger fool gull harpy jack jolthead knave liar lunatic maw milksop minion ratcatcher recreant rogue scold slave swine traitor varlet villain worm

```
$ ./abuse.py -h
usage: abuse.py [-h] [-a int] [-n int] [-s int]
Argparse Python script
optional arguments:
  -h, --help
                        show this help message and exit
  -a int, --adjectives int
                        Number of adjectives (default: 2)
  -n int, --number int Number of insults (default: 3)
  -s int, --seed int
                        Random seed (default: None)
$ ./abuse.py
You slanderous, rotten block!
You lubbery, scurilous ratcatcher!
You rotten, foul liar!
$ ./abuse.py -s 1 -n 2 -a 1
You rotten rogue!
You lascivious ape!
$ ./abuse.py -s 2 -n 4 -a 4
You scurilous, foolish, vile, foul milksop!
You cullionly, lubbery, heedless, filthy lunatic!
You foul, lecherous, infected, slanderous degenerate!
You base, ruinous, slanderous, false liar!
```

Skills

- \bullet Setting random seed from argument
- Random selecting/sampling from a list
- Iterating through a loop a defined number of times
- Formatting string output

abuse Solution

Blackjack

Write a Python program called blackjack.py that plays an abbreviated game of Blackjack. You will need to import random to get random cards from a deck you will construct, and so your program will need to accept a -s|--seed that will set random.seed() with the value that is passed in so that the test suite will work. The other arguments you will accept are two flags (Boolean values) of -p|--player_hits and -d|--dealer_hits. As usual, you will also have a -h|--help option for usage statement.

To play the game, the user will run the program and will see a display of what cards the dealer has (noted "D") and what cards the player has (noted "P") along with a sum of the values of the cards. In Blackjack, number cards are worth their value, face cards are worth 10, and the Ace will be worth 1 for our game (though in the real game it can alternate between 1 and 11).

To create your deck of cards, you will need to use the Unicode symbols for the suites () [which won't display in the PDF, so consult the Markdown file].

Combine these with the numbers 2-10 and the letters "A", "J", "Q," and "K" (hint: look at itertools.product). Because your game will use randomness, you will need to sort your deck and then use the random.shuffle method so that your cards will be in the correct order to pass the tests.

When you make the initial deal, keep in mind how cards are actually dealt – first one card to each of the players, then one to the dealer, then the players, then the dealer, etc. You might be tempted to use random.choice or something like that to select your cards, but you need to keep in mind that you are modeling an actual deck and so selected cards should no longer be present in the deck. If the -p|--player_htis flag is present, deal an additional card to the player; likewise with the -d|--dealer hits flag.

After displaying the hands, the code should:

- 1. Check if the player has more than 21; if so, print 'Player busts! You lose, loser!' and exit(0)
- 2. Check if the dealer has more than 21; if so, print 'Dealer busts.' and exit(0)
- 3. Check if the player has exactly 21; if so, print 'Player wins. You probably cheated.' and exit(0)
- 4. Check if the dealer has exactly 21; if so, print 'Dealer wins!' and exit(0)
- 5. If the either the dealer or the player has less than 18, you should indicate "X should hit."

NB: Look at the Markdown format to see the actual output as the suites won't display in the PDF version!

```
$ ./blackjack.py
D [11]: J A
P [18]: 8 10
Dealer should hit.
$ ./blackjack.py
D [13]: 3 J
P [16]: 6 10
Dealer should hit.
Player should hit.
$ ./blackjack.py -s 5
D [ 5]: 4 A
P [19]: 10 9
Dealer should hit.
$ ./blackjack.py -s 3 -p
D [19]: K 9
P [22]: 3 9 J
Player busts! You lose, loser!
$ ./blackjack.py -s 15 -p
D [19]: 10 9
P [21]: 10 8 3
Player wins. You probably cheated.
```

Family Tree

Write a program called tree.py that will take an input file as a single positional argument and produce a graph of the family tree described therein. The file can have only three kinds of statements:

```
    INITIALS = Full Name
    person1 married person2
    person1 and person2 begat child1[, child2...]
```

Use the graphviz module to generate a graph like the kyc.gv.pdf included here that was generated from the following input:

```
$ cat tudor.txt
H7 = Henry VII
EOY = Elizabeth of York
H8 = Henry VIII
COA = Catherine of Aragon
AB = Anne Boleyn
JS = Jane Seymour
AOC = Anne of Cleves
CH = Catherine Howard
CP = Catherine Parr
HDC = Henry, Duke of Cornwall
M1 = Mary I
E1 = Elizabeth I
E6 = Edward VI
H7 married EOY
H7 and EOY begat H8
H8 married COA
H8 married AB
H8 married JS
H8 married AOC
H8 married CH
H8 married CP
H8 and COA begat HDC, M1
H8 and AB begat E1
H8 and JS begat E6
$ ./tree.py tudor.txt
Done, see output in "tudor.txt.gv".
```

Gematria

Write a Python program called gematria.py

Gematria is a system for assigning a number to a word by summing the numeric values of each of the letters as defined by the Mispar godol (https://en.wikipedia.org/wiki/Gematria). For English characters, we can use the ASCII table (https://en.wikipedia.org/wiki/ASCII). It is not necessary, however, to encode this table in our program as Python provides the ord function to convert a character to its "ordinal" (order in the ASCII table) value as well as the chr function to convert a number to its "character."

```
>>> ord('A')
65
>>> ord('a')
97
>>> chr(88)
'X'
>>> chr(112)
'p'
```

To implement an ASCII version of gematria in Python, we need to turn each letter into a number and add them all together. So, to start, note that Python can use a for loop to cycle through all the members of a list (in order):

Now you just need to sum those up for each word!

```
$ ./gematria.py
usage: gematria.py [-h] str
gematria.py: error: the following arguments are required: str
$ ./gematria.py -h
usage: gematria.py [-h] str
```

Gematria

```
positional arguments:
```

str Input text or file

optional arguments:

- -h, --help show this help message and exit
- \$./gematria.py 'foo bar baz'
- 324 309 317
- \$./gematria.py ../inputs/fox.txt
 289 541 552 333 559 444 321 448 314

gematria Solution

```
1 #!/usr/bin/env python3
2 """Gematria"""
4 import argparse
5 import os
6 import re
7 import sys
9

Guessing Game

Write a Python program called guess.py that plays a guessing game for a number between a -m|--min and -x|--max value (default 1 and 50, respectively) with a limited number of -g|--guesses (default 5). Complain if either --min or --guesses is less than 1. Accept a -s|--seed for random.seed. If the user guesses something that is not a number, complain about it.

The game is intended to actually be interactive, which makes it difficult to test. Here is how it should look in interactive mode:

```
$ ./guess.py -s 1
Guess a number between 1 and 50 (q to quit): 25
"25" is too high.
Guess a number between 1 and 50 (q to quit): foo
"foo" is not a number.
Guess a number between 1 and 50 (q to quit): 12
"12" is too high.
Guess a number between 1 and 50 (q to quit): 6
"6" is too low.
Guess a number between 1 and 50 (q to quit): 9
"9" is correct. You win!
```

Because I want to be able to write a test for this, I also want the program to accept an -i|--inputs option so that the game can also be played exactly the same but without the prompts for input:

```
$ ./guess.py -s 1 -i 25 foo 12 6 9
"25" is too high.
"foo" is not a number.
"12" is too high.
"6" is too low.
"9" is correct. You win!
```

You should be able to handle this in your inifinite game loop.

Kentucky Fryer

Write a Python program called fryer.py that reads some input text from a single positional argument on the command line (which could be a file to read) and transforms the text by dropping the "g" from words two-syllable words ending in "-ing" and also changes "you" to "y'all". Be mindful to keep the case the same on the first letter, e.g, "You" should become "Y'all," "Hunting" should become "Huntin".

```
$ ./fryer.py
usage: fryer.py [-h] str
fryer.py: error: the following arguments are required: str
$ ./fryer.py -h
usage: fryer.py [-h] str
Southern fry text
positional arguments:
 str
              Input text or file
optional arguments:
 -h, --help show this help message and exit
$ ./fryer.py you
y'all
$ ./fryer.py Fishing
Fishin'
$ ./fryer.py string
string
$ cat tests/input1.txt
So I was fixing to ask him, "Do you want to go fishing?" I was dying
to go for a swing and maybe do some swimming, too.
$ ./fryer.py tests/input1.txt
So I was fixin' to ask him, "Do y'all want to go fishing?" I was dyin'
to go for a swing and maybe do some swimmin', too.

Markov Chains for Words

Write a Python program called markov.py that uses the Markov chain algorithm to generate new words from a set of training files. The program should take one or more positional arguments which are files that you read, word-by-word, and note the options of letters after a given $-k|--kmer_size$ (default 2) grouping of letters. E.g., in the word "alabama" with k=1, the frequency table will look like:

```
a = 1, b, m
1 = a
b = a
m = a
```

That is, given this training set, if you started with 1 you could only choose an a, but if you have a then you could choose 1, b, or m.

The program should generate $-n|--num_words$ words (default 10), each a random size between k+2 and a $-m|--max_word$ size (default 12). Be sure to accept -s|--seed to pass to random.seed. My solution also takes a -d|--debug flag that will emit debug messages to .log for you to inspect.

Chose the best words and create definitions for them:

- yulcogicism: the study of Christmas gnostics
- umjamp: skateboarding trick
- callots: insignia of officers in Greek army
- urchenev: fungal growth found under cobblestones

```
Kmer size (default: 2)
 -m int, --max_word int
                        Max word length (default: 12)
 -s int, --seed int
                        Random seed (default: None)
  -d, --debug
                        Debug to ".log" (default: False)
$ ./markov.py /usr/share/dict/words -s 1

Pig Latin

Write a Python program named piggie.py that takes one or more file names as positional arguments and converts all the words in them into "Pig Latin" (see rules below). Write the output to a directory given with the flags -ol--outdir (default out-yay) using the same basename as the input file, e.g., input/foo.txt would be written to out-yay/foo.txt.

if a file argument names a non-existent file, print a warning to STDERR and skip that file. If the output directory does not exist, create it.

Pig Latin Rules

- 1. If the word begins with consonants, e.g., "k" or "ch", move them to the end of the word and append "ay" so that "mouse" becomes "ouse-may" and "chair" becomes "air-chay."
- 2. If the word begins with a vowel, simple append "-yay" to the end, so "apple" is "apple-yay."

```
$ ./piggie.py
usage: piggie.py [-h] [-o str] FILE [FILE ...]
piggie.py: error: the following arguments are required: FILE
$ ./piggie.py -h
usage: piggie.py [-h] [-o str] FILE [FILE ...]
Convert to Pig Latin
positional arguments:

Soundex Rhymer

Write a Python program called rhymer.py that uses the Soundex algorithm/module (https://en.wikipedia.org/wiki/Soundex, https://pypi.org/project/soundex/) to find words that rhyme with a given input word. When comparing words, it would be best to discount any leading consonants, e.g., the words "listen" and "glisten" rhyme but only if you compare the "isten" part. The program should take an optional -w|--wordlist argument (default "/usr/share/dict/words") for the comparisons.

```
$ ./rhymer.py
usage: rhymer.py [-h] [-w str] str
rhymer.py: error: the following arguments are required: str
[cholla@~/work/python/playful_python/soundex-rhymer]$ ./rhymer.py -h

Substring Guessing Game

Write a Python program called sub.py that plays a guessing game where you read a -f|--file input (default /usr/share/dict/words) and use a given -k|--ksize to find all the words grouped by their shared kmers. Remove any kmers where the number of words is fewer than -m|--min_words. Also accept a -s|--seed for random.seed for testing purposes. Prompt the user to guess a word for a randomly chosen kmer. If their guess is not present in the shared list, taunt them mercilessly. If their guess is present, affirm their worth and prompt to guess again. Allow them to use! to quit and? to be provided a hint (a word from the list). For both successful guesses and hints, remove the word from the shared list. When they have quit or exhausted the list, quit play. At the end of the game, report the number of found words.

```
$ ./sub.py -h
usage: sub.py [-h] [-f str] [-s int] [-m int] [-k int]
Find words sharing a substring
optional arguments:
 -h, --help
                        show this help message and exit
 -f str. --file str
                        Input file (default: /usr/share/dict/words)
 -s int, --seed int
                        Random seed (default: None)
  -m int, --min_words int

Tic-Tac-Toe Outcome

Create a Python program called outcome.py that takes a given Tic-Tac-Toe state as it's only (positional) argument and reports if X or O has won or if there is no winner. The state should only contain the characters ".", "O", and "X", and must be exactly 9 characters long. If there is not exactly one argument, print a "usage" statement.

```
$ ./outcome.py
Usage: outcome.py STATE
$ ./outcome.py ..X.OA..X
State "..X.OA..X" must be 9 characters of only ., X, O
$ ./outcome.py ..X.OX...
No winner
$ ./outcome.py ..X.OX..X
X has won
```

Twelve Days of Christmas

Write a Python program called twelve_days.py that will generate the "Twelve Days of Christmas" song up to the -n|--number_days argument (default 12), writing the resulting text to the -o|--outfile argument (default STDOUT).

```
$ ./twelve_days.py -h
usage: twelve_days.py [-h] [-o str] [-n int]
Twelve Days of Christmas
optional arguments:
 -h, --help
                        show this help message and exit
 -o str, --outfile str
                        Outfile (STDOUT) (default: )
 -n int, --number days int
                        Number of days to sing (default: 12)
$ ./twelve_days.py -n 1
On the first day of Christmas,
My true love gave to me,
A partridge in a pear tree.
$ ./twelve_days.py -n 3
On the first day of Christmas,
My true love gave to me,
A partridge in a pear tree.
On the second day of Christmas,
My true love gave to me,
Two turtle doves,
And a partridge in a pear tree.
On the third day of Christmas,
My true love gave to me,
Three French hens,
Two turtle doves,
And a partridge in a pear tree.
$ ./twelve days.py -o out
$ wc -l out
     113 out

War

The generation of random numbers is too important to be left to chance. – Robert R. Coveyou

Create a Python program called "war.py" that plays the card game "War." The program will use the random module to shuffle a deck of cards, so your program will need to accept a -s|--seed argument (default: None) which you will use to call random.seed, if present.

First you program will need to create a deck of cards. You will need to use the Unicode symbols for the suites () [which won't display in the PDF, so consult the Markdown file] and combine those with the numbers 2-10 and the letters "J", "Q," "K," and "A." (hint: look at itertools.product).

```
>>> from itertools import product
>>> a = list('ABC')
>>> b = range(3)
>>> list(product(a, b))
[('A', 0), ('A', 1), ('A', 2), ('B', 0), ('B', 1), ('B', 2), ('C', 0), ('C', 1), ('C', 2)]
```

NB: You must sort your deck and then use the random.shuffle method so that your cards will be in the correct order to pass the tests!

In the real game of War, the cards are shuffled and then dealt one card each first to the non-dealer, then to the dealer, until all cards are dealt and each player has 26 cards. We will not be modeling this behavior. When writing your version of the game, simply pop two cards off the deck as the cards for player 1 and player 2, respectively. Compare the two cards by ignoring the suite and evaluating the value where 2 is the lowest and Aces are the highest. When two cards have the same values (e.g., two 5s or two Jacks), print "WAR!" In the real game, this initiates a sub-game of War which is a "recursive" algorithm which we will not bother modeling. Keep track of which player wins each round where no points are awarded in a tie. At the end, report the points for each player and state the winner. In the event of a tie, print "DRAW."

Hangman

Write a Python program called hangman.py that will play a game of Hangman which is a bit like "Wheel of Fortune" where you present the user with a number of elements indicating the length of a word. For our game, use the underscore _ to indicate a letter that has not been guessed. The program should take -n|--minlen minimum length (default 5) and -l|--maxlen maximum length options (default 10) to indicate the minimum and maximum lengths of the randomly chosen word taken from the -w|--wordlist option (default /usr/share/dict/words). It also needs to take -s|--seed to for the random seed and the -m|--misses number of misses to allow the player.

To play, you will initiate an inifinite loop and keep track of the game state, e.g., the word to guess, the letters already guessed, the letters found, the number of misses. As this is an interactive game, I cannot write an test suite, so you can play my version and then try to write one like it. If the user guesses a letter that is in the word, replace the _ characters with the letter. If the user guesses the same letter twice, admonish them. If the user guesses a letter that is not in the word, increment the misses and let them know they missed. If the user guesses too many times, exit the game and insult them. If they correctly guess the word, let them know and exit the game.

```
$ ./hangman.py -h
usage: hangman.py [-h] [-1 MAXLEN] [-n MINLEN] [-m MISSES] [-s SEED]
                  [-w WORDLIST]

Markov Chain

Write a Python program called markov.py that takes one or more text files as positional arguments for training. Use the -n|--num_words argument (default 2) to find clusters of words and the words that follow them, e.g., in "The Bustle" by Emily Dickinson:

The bustle in a house The morning after death Is solemnest of industries Enacted upon earth,-

The sweeping up the heart, And putting love away We shall not want to use again Until eternity.

If n=1, then we find that "The" can be followed by "bustle," "morning," and "sweeping. There is a "the" followed by "heart," but we're not going to alter the text in any way, including removing punctuation, so just use str.split on the text to break up the words.

To begin your text, choose a random word (or words) that begin with an uppercase letter. Then randomly select the next word in the chain, keep track of the floating window of the -n words, and keep selecting the next words until you have matched or exceeded the -l|--length argument of the number of characters (default 500) to emit at which point you should stop when you find a word that terminates with ., !, or ?.

If you use str.split to get the words from the training text, you'll be removing any newlines from the text, so use a -w|--text_width argument (default 70) to introduce newlines in the output before the text exceeds that number of characters on the line.

Because of the use of randomness, you should include a -s|--seed argument (default None) to pass to random.seed.

Occassionally you may chose a path that terminates. That is, in selecting the next word, you may find there is no next-next word. In that case, just exit the program.

My implementation includes a -d|--debug option that will write a .log file so you can inspect my data structures and logic as you write your own version.

You should find many diverse texts and use them all as training files with varying numbers for -n to see how the texts will be mixed. The results are endlessly

entertaining.

```

Chapter 31

Morse Encoder/Decoder

Write a Python program called morse.py that will encrypt/decrypt text to/from Morse code. The program should expect a single positional argument which is either the name of a file to read for the input or the character - to indicate reading from STDIN. The program should also take a -c|--coding option to indicate use of the itu or standard morse tables, -o|--outfile for writing the output (default STDOUT), and a -d|--decode flag to indicate that the action is to decode the input (the default is to encode it).

```
$ ./morse.py
usage: morse.py [-h] [-c str] [-o str] [-d] [-D] FILE
morse.py: error: the following arguments are required: FILE
$ ./morse.py -h
usage: morse.py [-h] [-c str] [-o str] [-d] [-D] FILE
Encode and decode text/Morse
positional arguments:
 FILE
                        Input file or "-" for stdin
optional arguments:
 -h, --help
                        show this help message and exit
  -c str, --coding str Coding version (default: itu)
 -o str, --outfile str
                        Output file (default: None)
 -d, --decode
                        Decode message from Morse to text (default: False)
  -D, --debug
                        Debug (default: False)
$ ./morse.py ../inputs/fox.txt
- .... . --.- ..- .. -.-. -.- -... .-. --- .-- -. ..-. --- -..- .--- ..- .-- .-.
```

[cholla@~/work/python/playful_python/morse]\$./morse.py ../inputs/fox.txt | ./morse.py -d - THE QUICK BROWN FOX JUMPS OVER THE LAZY DOG.

Chapter 32

ROT13 (Rotate 13)

Write a Python program called rot13.py that will encrypt/decrypt input text by shifting the text by a given -s|--shift argument or will move each character halfway through the alphabet, e.g., "a" becomes "n," "b" becomes "o," etc. The text to rotate should be provided as a single positional argument to your program and can either be a text file, text on the command line, or - to indicate STDIN so that you can round-trip data through your program to ensure you are encrypting and decrypting properly.

The way I approached the solution is to think of adding time. If it's 8 in the morning and I want to know the time in 6 hours on a 12-hour (not military/24-hour) clock, I need to think in terms of 12 when the clock rolls over from AM to PM. To do that, I need to know the remainder of dividing by 12, which is given by the modulus % operator:

```
>>> now = 8
>>> (now + 6) % 12
2
```

And 6 hours from 8AM is, indeed, 2PM.

Similarly if I want to know how many hours (in decimal) are a particular number of minutes, I need to mod by 60:

```
>>> minutes = 90

>>> int(minutes / 60) + (minutes % 60) / 60

1.5

>>> minutes = 204

>>> int(minutes / 60) + (minutes % 60) / 60

3.4
```

If you import string, you can see all the lower/uppercase letters

```
>>> import string
>>> string.ascii_lowercase
'abcdefghijklmnopqrstuvwxyz'
>>> string.ascii_uppercase
'ABCDEFGHIJKLMNOPQRSTUVWXYZ'
```

So I think about "rot13" like adding 13 (or some other shift interval) to the position of the letter in the list and modding by the length of the list to wrap it around. If the shift is 13 and we are at "a" and want to know what the letter 13 way is, we can use pos to find "a" and add 13 to that:

```
>>> lcase = list(string.ascii_lowercase)
>>> lcase.index('a')
```

```
>>> lcase[lcase.index('a') + 13]
But if we want to know the value for something after the 13th letter in our list,
we are in trouble!
>>> lcase[lcase.index('x') + 13]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
IndexError: list index out of range
% to the rescue!
>>> lcase[(lcase.index('x') + 13) % len(lcase)]
It's not necessary in this algorithm to shift by any particular number. 13 is
special because it's halfway through the alphabet, but we could shift by just 2
or 5 characters. If we want to round-trip our text, it's necessary to shift in the
opposite direction on the second half of the trip, so be sure to use the negative
value there!
$ ./rot13.py
usage: rot13.py [-h] [-s int] str
rot13.py: error: the following arguments are required: str
$ ./rot13.py -h
usage: rot13.py [-h] [-s int] str
Argparse Python script
positional arguments:
                        Input text, file, or "-" for STDIN
  str
optional arguments:
                        show this help message and exit
  -h, --help
  -s int, --shift int Shift arg (default: 0)
$ ./rot13.py AbCd
NoPq
$ ./rot13.py AbCd -s 2
CdEf
$ ./rot13.py fox.txt
Gur dhvpx oebja sbk whzcf bire gur ynml qbt.
$ ./rot13.py fox.txt | ./rot13.py -
The quick brown fox jumps over the lazy dog.
$ ./rot13.py -s 3 fox.txt | ./rot13.py -s -3 -
```

The quick brown fox jumps over the lazy dog.
